A Joint Usage/Research Center approved by the Japanese Ministry of Education, Culture, Sports, Science and Technology and one of the WOAH Collaborating Centres

National Research Center for Protozoan Diseases

Mission

Our mission, as the only MEXT Joint Usage/Research Center of Protozoan Diseases in Japan, is to promote cutting-edge research on the control of protozoan diseases in humans and livestock. This research is conducted to contribute to the health and welfare of human beings as well as to the global issue of food safety and security. This will be accomplished through cooperation with domestic and foreign universities, relevant

Message from the Director General

Noboru Inoue

The National Research Center for Protozoan Diseases (NRCPD) of Obihiro University of Agriculture and Veterinary Medicine was established as an inter-university joint-use facility in 1990, certified as a national joint-use facility in 2000, and then as a joint-use facility/research center in 2009 by the Ministry of Education, Culture, Sports, Science and Technology. In addition, in terms of collaborative activities with related international organizations, our two professors were appointed as Reference Laboratory (RL) experts by the World Organization for Animal Health (WOAH) in 2007, and the following year, NRCPD was recognized as the first WOAH Collaborating Center in the world in the field of protozoan diseases. In 2017, the WOAH RL developed an international standard diagnostic testing system by obtaining ISO/IEC 17025 accreditation for the diagnostic tests provided by the WOAH RL. In collaboration with WOAH and other relevant international organizations, we will continue to contribute to the global surveillance and control of protozoan diseases through academic research and international human resource development. As an example, since 1995, with the support of the Japan International Cooperation Agency (JICA), NRCPD has invited experts from emerging and developing countries who are involved in zoonotic disease control, mainly protozoan diseases, and has conducted group training courses. Nearly 243 trainees have so far completed the course and are now playing a central role in veterinary and livestock administration and infectious disease research and education in their respective countries. Our network of international researchers consisting of these graduates has become an important human resource in the internationalization of education and research activities at the University as well as at NRCPD.

The damage caused to humans and animals by protozoan diseases is immeasurable. Protozoan parasites are tough enemies with a high similarity to host cells and sophisticated survival strategies such as antigenic variations, immune disruption, and complex life cycles. Unfortunately, there are still few prophylactic vaccines or safe treatments available. Therefore, the development of inexpensive diagnostic, prophylactic, and therapeutic methods that can be practically applied in livestock farms around the world is an urgent issue on a global scale. NRCPD will contribute to One Health issue resolution and promotion by actively promoting international collaborative research based on our global network of protozoan disease researchers.

International Contribution/Development of Human Resources

The National Research Center for Protozoan Diseases, in collaboration with the Japan International Cooperation Agency (JICA), has provided training programs on zoonotic protozoan diseases to backbone and senior administrative technical researchers from developing countries, especially Asian and African nations, since 1995. Over 243 graduates working as advanced technical researchers perform zoonoses measures in their respective countries and act as important counterparts for the international joint research project. We also provide graduates the opportunity to join our research center for 3-6 months to re-train their professional skills and develop collaborative research projects with us. We accept 3~5 re-trainees every fiscal year.

International Joint Research Center

Many protozoan diseases persistently infect livestock, causing anemia and miscarriages and worsening their chronic health condition. However, accurate means of diagnosis, prophylactic vaccines and safe specific medicines are not available for protozoan diseases. The detrimental effects of protozoan diseases on livestock must therefore be resolved on a global scale as quickly as possible. The National Research Center for Protozoan Diseases, as the international joint research center for protozoan diseases of animals in the world, has clarified the distribution and damage caused by these diseases by conducting a large-scale epidemiological survey using diagnostic technology developed in-house. Moreover, we train

young specialists throughout the world through these kinds of activities at the international joint research center. The center also continues to develop and make contributions to research on protozoan diseases, as well as maintaining an early recognition system and thereby contributing to the prevention of these diseases in livestock and thus to the development of the international livestock industry.

Cooperation countries:

The United States of America, Mongolia, China, Taiwan, South Korea, Philippines, Thailand, Vietnam, Indonesia, Sri Lanka, Egypt, Kenya, Uganda, Tanzania, Benin, Burkina Faso, South Africa, Turkey, India, Germany, Poland, Argentina and Mexico

Investigation of ticks that transmit protozoa in China

WOAH Reference Laboratory and Collaborating Centre

The World Organization for Animal Health (WOAH), an international organization with 183 member countries, aims to ensure the security and safety of livestock and livestock products. They certify the world's cutting-edge research institutes and specialists as collaborating centres (CC) or reference laboratories (RL). These institutes then utilize the results of the latest research for the development of new diagnostic methods for infectious diseases in animals and are responsible for the international standardization of vaccines. In recent years, WOAH has also emphasized the contribution of CCs to developing countries so that diagnostic

technology for infectious diseases and livestock sanitation standards can be improved in these countries. In June 2007, our two professors were designated as WOAH RL experts (bovine babesiosis, equine piroplasmosis and surra). In May 2008, the National Research Center for Protozoan Diseases (NRCPD) was designated as the first WOAH CC in Asia. NRCPD is highly expected to contribute for the control of zoonotic protozoan diseases in the world. Moreover, "protozoan DNA testing of bovine babesiosis, equine piroplasmosis and surra by PCR methods in accordance with WOAH Manual" provided by WOAH RLs has been certified as ISO/IEC17025:2017 in April 2021.

Professor Yoshifumi Nishikawa

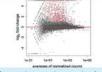

We are researching functional disorders of the central nervous system (CNS) and behavioral changes in host animals, as well as the mechanism of miscarriage or vertical transmission of protozoan infections. In addition, we are attempting to identify and analyze parasite-derived

factors that control inflammatory response and immuno-suppression. Based on the results of this research, we are developing a new type of next-generation vaccine that can effectively transport a vaccine antigen to lymphoid tissues by utilizing multifunctional materials and can effectively stimulate immune cells. For practical application of our vaccine, we investigate the effects of the model vaccine based on infection models of mice and natural hosts.

[Main Research Projects]

- Study on behavioral changes of host animals and CNS disorder following Toxoplasma and Neospora infection.
- · Study on immune evasion mechanisms of Toxoplasma and Neospora
- Pathological study of malaria, toxoplasmosis, neosporosis and cryptosporidiosis
- · Vaccine development based on multifunctional materials
- Screening of anti-parasite drug from natural products
- · Study on intestinal flora associated with bovine diarrhea

Cyst of Toxoplasma in brain tissue

Comparative transcriptome using the brain tissue of a mouse infected with Toxoplasma infected with Neospora

Department of Drug Discovery and Development

Specially Appointed Assistant Professor Nanako Ushio-Watanabe

We are researching the pathology of parasite infections in animals and humans by using pathological analysis. Specifically, we focus on chronic infection in the central nervous system and acute and chronic infection in the retina caused by Toxoplasma and Neospora, as well as

the infection during pregnancy.

· Chronic infection in the central nervous system:

Toxoplasma and Neospora form cysts in the brain and cause lifelong chronic infections. Chronic infection with *Toxoplasma* has been reported to induce behavioral changes in the host. We are studying the pathogenesis and the impact of parasite-derived molecules that cause behavioral changes in the host.

• Acute and chronic infection in the retina: Toxoplasma infection, both congenital and acquired, can lead to inflammation in the retina, which result in blindness. We are focusing on Müller glial cells in the retina to analyze the pathogenesis of this condition.

Research Unit for Innovative Medicine

 Infection during pregnancy: Toxoplasma and Neospora infections can cause miscarriage and neonatal infections. We analyze on mouse model of congenital infection and studying the pathogenesis of vertical transmission and postpartum depression.

Department of Drug Discovery and Development

Specially Appointed Assistant Professor Rie Kubota

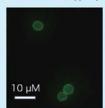

We are researching the cellular parasitic mechanisms of Cryptosporidium, which causes diarrhoea in humans and animals. Cryptosporidium parasites infect all mammals including humans and animals. There is no effective vaccine or prophylactic drug, and Cryptosporidium infection,

especially in calves, causes lethal diarrhoea, resulting in economic losses to the cattle industry, including Japan. Parasites invade intestinal epithelial cells and shed their seeding (oocysts) by sexual reproduction, but the detailed mechanisms of parasitism and development are not clear. We aim to understand the parasitic strategies of Cryptosporidium parasites, including the analysis of their gene function, using genetic modification techniques.

[Main Research Projects]

- Elucidation of the cellular invasion mechanism of Cryptosporidium parasite
- Discovery of anti-cryptosporidium parasite drugs
- Development of in vitro culture systems for Cryptosporidium parasite
- · Study on the intestinal microflora associated with Cryptosporidium infection
- · Discovery of vaccine antigens

Cryptosporidium oocysts from bovine faeces (immunofluorescen staining)

Department of Global Cooperation

Professor Shin-ichiro Kawazu

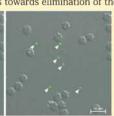

We are developing technology to manipulate genes using Babesia. So far, we have developed a foreign gene expression system (green fluorescent protein-expressing protozoa) and a

gene knockout system, and we are currently trying to use live imaging to clarify the mechanism of the said protozoa's growth and infection into the red cells and the vector tick; and the pathology of cerebral babesiosis.

Japanese bilharziasis

Japanese bilharziasis is a zoonotic disease closely related to public and animal health in rural areas of Asian countries. We are developing ELISA and POCT as suitable and affordable diagnostic tools, and are conducting comprehensive epidemiological surveys with the newly developed ELISA protocol and population genetic tools towards elimination of the disease in the Philippines.

Hyper (H2O2 sensor probe) expressing Babesia bovis

Department of Global Cooperation

babesiosis.

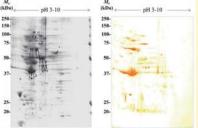

Professor Xuenan Xuan

The main focus of this lab is to elucidate the host defense mechanisms against protozoan diseases, and to develop medical agents and recombinant vaccines that could efficiently stimulate

the host protective immunity.

Main Research Projects

- Elucidation of the mechanism of hemolytic anemia caused by babesiosis.
- Analysis of the host protective immunity against babesiosis.
- O Identification of genome-wide metabolic pathways and vaccine candidate molecules of Babesia parasites.
- O Development of moleculetargeting treatments and recombinant vaccines against
- O International epidemiological surveys of tick-borne protozoan diseases.

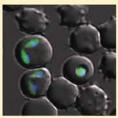

Proteomic analysis of autoimmunity against platelets caused by Babesia parasite infection.

Associate Professor Masahito Asada

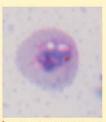

Babesia and Plasmodium parasites are intraerythrocytic apicomplexan protozoans which cause sever morbidity and mortality to the animals and humans in the world. These

parasites invade into the host erythrocytes and extensively modify structural and mechanical properties of the erythrocytes. To find a way to control babesiosis and malaria, we are studying on invasion and host erythrocyte modification mechanisms of the parasites by using genome manipulation techniques. Furthermore, we are performing field epidemiology of protozoan diseases.

- O Mechanisms of parasite invasion into the erythrocyte
- O Mechanisms of erythrocyte modification by the parasites
- O Field epidemiology of protozoan diseases

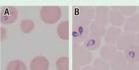

Genome editing by CRISPR/ Ungulate malaria parasite

Professor Naoaki Yokoyama

Bovine and equine piroplasmosis (babesiosis and theileriosis) caused by species of genera Babesia and Theileria is characterized by fever and anemia. The disease usually results in severe economic losses in cattle and horse industry worldwide. Therefore, control and

prevention of bovine and equine piroplasmosis through surveillance and risk factor identification are vital. As WOAH reference laboratories for bovine babesiosis and equine piroplasmosis, we survey the cattle and horses on a global scale to ascertain the current epidemiological status of *Babesia* and *Theileria* species, determine their genetic diversity, identify the risk factors, and discover novel parasite species with clinical importance. We also develop methods and scientific tools to aid better research and diagnosis. Moreover, we provide diagnostic services and materials to WOAH member countries to improve control and preventive efforts, particularly to prevent the spread of infections through the transnational movement of animals. To accelerate our goal of minimizing bovine and equine piroplasmosis, we maintain a robust international collaborative network and welcome postgraduate students and young postdoctoral researchers for the development of human resources in countries where these diseases are endemic.

Tick (A) and cattle (B) in Mongolia

Associate Professor Rika Umemiya-Shirafuji

Ticks are obligatory hematophagous arthropods and are known to be important vectors for various pathogens in vertebrates, such as Babesia and Theileria parasites. Our laboratory focuses on the molecular mechanisms underlying nutrient metabolism in unfed or

fed ticks and tick oogenesis. Our aim is to contribute to the development of new methods for controlling ticks and tick-borne pathogens.

Nutrient metabolism in unfed ticks

Most hard tick species have a life span of several months or years. Their life is essentially composed of relatively short parasitic periods and long non-feeding periods, without intake of blood. This remarkable viability is important for understanding the biology and epidemiology of ticks and tick-borne pathogens.

Nutrient metabolism in fed ticks

Energy and nutrient reserves provided by digestion of a blood meal in female ticks allow the synthesis of vitellogenin (Vg), the yolk protein precursor. Synthesis and uptake of Vg are essential processes in the oogenesis of ticks.

O Vector biology

Using ticks infected with parasites, we are studying the relationship between transmission of parasites and nutrient metabolism of ticks.

Department of Disease Control

Professor Noboru Inoue

As an WOAH Reference Laboratory (WOAH RL) Expert for Surra, I am in charge in periodic revisions of the WOAH documents, such as Animal Health Code and the WOAH Manual, in collaboration with other WOAH RL Experts. I also provide

definitive diagnosis of Surra at the request of international clients involved in the import and export of livestock, pets, and zoo exhibit animals, and conduct research on development of new diagnostic methods for trypanosomoses.

We are conducting research to clarify the interaction between Trypanosoma and vectors/hosts at the molecular level. We particularly focused on the epimastigote (EMF) stage-specific cell surface molecules involving cell adhesion in tsetse salivary gland. We have so far discovered two EMF stage-specific surface proteins, CESP (function unknown) and TcEpHbR (hemoglobin receptor).

Development of simple/rapid diagnostic methods and social implementation research of epidemiological studies for practical use in endemic areas are being conducted. We have established Mongolian office and research facilities at the Institute of Veterinary Medicine, Mongolia, and are conducting collaborative research on animal trypanosomoses, which are serious concern in Mongolia, and are conducting joint research for the practical application of diagnostic methods and control measures for the protozoan disease

Our diagnostic kits are practically used in Mongolia

WOAH-NTTAT Network Meeting at Trypanosome sampling WOAH-HQ

from dourine horse

Associate Professor Keisuke Suganuma

Trypanosomoses are endemic in many countries and affect both humans and animals. However, no effective control measures are available for this disease. We therefore aim to develop and establish effective control strategies for trypanosomoses.

Studies on developmental-stage conversion mechanisms. (Fig. 1)

Developmental-stage conversion (or cell differentiation) is essential for trypanosomes to parasitize mammalian hosts and vectors. Therefore, we aim to reveal the stage conversion mechanisms using gene manipulation technology, with the aim of developing new control strategies for trypanosomoses.

Global surveillance and establishment of new laboratory strains of trypanosomes. (Fig. 2) We aim to establish effective control strategies for trypanosomoses in endemic countries based on field surveillance data. In addition, we intend to isolate and

establish field strains of trypanosomes for further study.

Development of novel trypanocidal drugs.

Research Unit for Advanced Preventive Medicine

We aim to find novel trypanocidal compounds by using in vitro drug screening systems and mouse models

Department of Disease Control

Professor Makoto Igarashi

Toxoplasmosis is a zoonotic disease latently infecting 20% to 30% of the world's population. Toxoplasma causes serious problems in immune-suppressed people such as HIV patients and the elderly as

well as in congenitally infected infants. This laboratory is working on unraveling the mechanism of Toxoplasma's parasitism in hosts.

Main Research Project

Understanding Toxoplasma's parasitism in host cells:

We aim to identify target molecules for new medicines by isolating molecules involved in Toxoplasma's parasitism in host cells.

OUnderstanding the transition process from acute to chronic *Toxoplasma* infection: During the transition from an acute to a chronic infection Toxoplasma changes its life cycle from a propagation type to a cyst-forming type. By uncovering the mechanism of this change we aim to utilize it for vaccine development strategies.

Stage conversion of Toxoplasma

Identification of the

Creation of a GRA22 gene knockout strain

Is GRA22 involved in egress from host cells?

Research Unit for Infection and Pathology

Associate Professor Shinya Fukumoto

Certain infectious diseases such as malaria, sleeping sickness, Japanese encephalitis, and filariasis are transmitted by arthropods. The transmission of these infectious diseases requires "vectors". In

other words, if the vector stage is cut off, infections of animals and humans can be avoided. Based on this concept, we raise the following questions: How do etiological agents behave within vectors? How do a vector and an etiological agent interact with each other? What are etiological agents to vectors in the first place? We are researching the items above in an effort to achieve the suppression of protozoan diseases by controlling the vector stage. We systematically integrate a wide range of information, from data generated by basic laboratory experiments to field research in endemic areas, as well as thoroughly analyzing unique life phenomena caused by the relationship between such etiological agents and vectors.

Base of Activities

As an international joint research center for the control of protozoan diseases, the National Research Center for Protozoan Diseases develops technology for the diagnosis, prevention and treatment of livestock protozoan diseases in domestic and foreign countries. We utilize an experimental system that simulates the life cycle of each protozoon in nature (experimental system of authentic infection). In addition, we use WOAH Collaborating Centre-related research to promote developmental research into technology relating to protozoan disease prevention that will

Online International Symposium on Ticks as a Joint Usage/Research Center Project

become the international standard. In the 4th mid-term target period, we are conducting a national project entitled "Establishment of a comprehensive drug discovery research center utilizing the analysis matrix for livestock protozoan diseases (Drug Discovery Project)". For the development of new therapeutic agents for livestock protozoan diseases, screening of candidate compounds and studies of their mechanism of action are underway. The goal of this project is establishment of "research center for drug discovery on livestock protozoan diseases" with a view to realizing social implementation.

Social Contribution Activity

We offer diagnostic services for infectious diseases, especially protozoan diseases, in domestic animals in cooperation with the Veterinary Medical Center at Obihiro University of Agriculture and Veterinary Medicine to help the community with our research achievements. We also provide extremely advanced and specialized diagnostic services for protozoan diseases that have been developed by the National Research Center for Protozoan Diseases. Moreover, as a core research institute for protozoan

Special diagnostic service for infectious diseases

diseases, we would like to contribute to the development of protozoan disease research worldwide. We therefore provide bioresources such as protozoan parasites, ticks, cDNA libraries, and monoclonal antibodies. Information about the bioresources offered

is openly available on our home page. Furthermore, by establishing and providing systems of bioassay for pathogenic protozoan parasites, we contribute actively to development of anti-protozoal agents.

HISTORY

I The Laboratory for Protozoan Immunology (1984-1990)

April 1984. The Laboratory for Protozoan Immunology was established as an annex of the Department of Veterinary Physiology (Prof. Em. Naoyoshi SUZUKI)

II The Research Center for Protozoan Molecular Immunology (1990-2000) June 1990 The Research Center for Protozoan Molecular Immunology granted permission

by MEXT, and established as a Joint Research-Educational Facility at Obihiro University until March 31, 2000. Research Unit of Molecular Immunology was established.

April 1992 Research Unit of Pathophysiology, established.

June 1993 New research building constructed with 462m area.

April 1995 Research Unit of Disease Control and Genetics, established. April 1997 Research Unit of Molecular Arthropodology, established.

November 1997 New research building constructed with 970ml area.

III National Research Center for Protozoan Diseases (2000 to the present)

April 2000 Establishment of the "National Research Center for Protozoan Diseases:NRCPD" as a national research facility covering a 10 year period (2000-2010). Research Unit for Molecular Diagnosis and Research Unit for Advanced Preventive Medicine, established.

March 2002 Extension of research building completed with 1,730 nf area.

October 2002 NRCPD recognized and selected to implement

the "21st Century Center of Excellence (COE) Program", by MEXT.

Department of Large Animal Infections, established. April 2003

Department of Global Surveillance of Protozoan Diseases, April 2005 established with the three Research Units.

March 2006 Extension of research building completed with 1,520 m area Certified as an WOAH Reference Laboratory (bovine babesiosis June 2007

and equine piroplasmosis: Prof. Igarashi, surra: Prof. Inoue). Certified as an WOAH Collaborating Centre (the first facility in the May 2008

world in the field of protozoan diseases).

Certified as the Joint Usage Research Center by MEXT. June 2009 Bio-Self Regulating Science Laboratory November 2012

(Hakuju donated fund laboratory), established.

Research Unit for Global Infection Control, established March 2013

(Tenure-Track Promotion Program, JST).

April 2016 Re-certified as the Joint Usage Research Center by MEXT.

March 2017 Certified as ISO/IEC17025:2005

(Bovine babesiosis, Equine piroplasmosis, and Surra).

Research Unit for International Surveillance, established January 2018

April 2022 Re-certified as the Joint Usage Research Center by MEXT.

April 2022 Department of Drug Discovery and Development,

Research Unit for Innovative Medicine, established

Access to us

From Obihiro Station to the University

Tokachi Bus

There are 2 bus routes from Obihiro Station to the University.

①From Obihiro Station Bus Terminal #9, take bus #70 or #72 bound for Oozora Danchi.

Get off at Ryokuyou Koko Mae Bus Stop. (about 30 min.)

It's about a 15 min. walk to the University entrance.

2 From Obihiro Station Bus Terminal #9, take bus #73 bound for ito yokado.

Get off at Nougyou Koko seimon kita Mae Bus Stop. (about 30 min.)

It's about a 15 min. walk to the University entrance.

It takes about 20 min. and costs around 2,400 yen (about 7 km).

From Tokachi-Obihiro Airport to the University

Tokachi Bus

There is a bus from the airport to Obihiro Station. (about 40 min., 1,000 yen) From Obihiro Station see schedule shown above.

It takes about 30 min. by taxi and costs around 7,000 yen (about 21 km).
